Within the Fulgoromorpha, the Lophopidae have been recognized as a paraphyletic taxon (Soulier *et al.*, 1996). The Neotropical genera *Hesticus* and *Silvanana* have been shown to be more closely related to the Ricaniidae. All the other lophopid genera form a monophyletic group characterised by three synapomorphies:

- Enlarged apex of the anal tube,
- Gonocoxae IX absent,
- Gonospiculum absent.

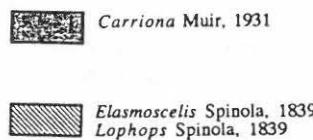

Two main monophyletic clades are recognised, *Menosca*⁺ and *Paracorethrura*⁺. The ornamentation of the bursa copulatrix is characteristic for *Menosca*⁺ and for *Paracorethrura*⁺, the first hind tarsal segment bearing a pad of micro setae. In the basal lophopid genera, the group *Jugoda*⁺ is characterised by its autapomorphic elevated lateral carina of the vertex.

This family is essentially found in the Oriental and Australasian regions with the exception of (i) *Lophops* and *Elasmoscelis* which are also present in Africa and (ii) *Carriona* found in the Neotropical region. From a biogeographical point of view, the two monophyletic ingroups recognised, *Menosca*⁺ and *Paracorethrura*⁺ appear coherent. *Carriona*, the last neotropical genera still placed within the Lophopidae and apparently allied to the *Jugoda*⁺ group, presents a transpacific paradoxical track.
